

TITLE OF THE INVENTION

PRINTING CONTROL METHOD, APPARATUS AND STORAGE MEDIUM  
THEREFORE, AND PRINTING SYSTEM

5

FIELD OF THE INVENTION

This invention relates to a printing control method  
and apparatus for performing printing based upon print  
10 data to which user identification information has been  
attached, and to a storage medium storing a program for  
implementing this control method.

BACKGROUND OF THE INVENTION

15

In a known printing system, a user employs a host  
computer to create print data upon attaching password  
information (identification information) and to transmit  
the print data to a printer so that confidential  
20 printing can be performed. In this case, the printing  
apparatus is capable of printing the print data only  
when the user enters the correct password information  
that was attached to the print data.

If the printing apparatus is a shared printer  
25 connected to a network, such a printing system is useful  
when a user does not wish another person to see a  
printout or when a document having confidential items or

the like that must not be revealed to other parties is to be printed.

With a conventional printing system of this kind, however, the secrecy of a printout is maintained but such information as the name of the confidential document and the name of the transmitting party is displayed on the control panel of the printing apparatus. The result is a decline in confidentiality regarding displayed document and user names.

#### SUMMARY OF THE INVENTION

Accordingly, an object of the present invention is to provide a printing control method, apparatus, storage medium and printing system in which the confidentiality of print processing is enhanced by making it possible to change at least the document name or user name associated with a print job.

In order to attain the above object, the printing control apparatus of the present invention is a printing control apparatus for performing printing by a printing device based upon a print job, comprises: setting means for setting identification information corresponding to the print job, and modifying means for enabling modification of at least one of a user name and document name of the print job to which the identification information set by said setting means has been appended.

Further, in order to attain the above object, the printing control method of the present invention is a printing control method in a printing system having a host computer for creating a print job, and a printing device for performing printing upon receiving the print job from the host computer. The method comprises a setting step of setting identification information corresponding to the print job; a modifying step of modifying of at least one of a user name and document name of the print job to which the identification information set in said setting step has been appended; a step of transmitting the print job to said printing device; a determination step of inputting identification information and determining whether this identification information matches identification information corresponding to a received job; and a step of executing the print job corresponding to said identification information if a match is determined at said determination step.

Other features and advantages of the present invention will be apparent from the following description taken in conjunction with the accompanying drawings, in which like reference characters designate the same or similar parts throughout the figures thereof.

#### BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of the specification, illustrate embodiments of the invention and, together with the description, serve to explain the principle of the invention.

#### DESCRIPTION OF THE PREFERRED EMBODIMENTS

Preferred embodiments of the present invention will now be described in detail with reference to the accompanying drawings.

[First Embodiment]

Fig. 1 is a block diagram useful in describing the configuration of a printer control system according to an embodiment of the present invention. It should be  
5 noted that as long as the functions according to this embodiment are implemented, then, if not stated otherwise, the arrangement of the invention may be a stand-alone device, a system comprising a plurality of devices or a system in which processing is executed upon  
10 making a connection via a network such as a LAN or WAN. Further, the printing control apparatus of the present invention may be incorporated in the printing apparatus of a printer or may be an apparatus that is connected to a printing apparatus via a LAN or the like in order to  
15 control the printing apparatus, as in the manner of a host computer.

The system shown in Fig. 1 includes a host computer 3000 having a CPU 1 which, on the basis of a program ROM in a ROM 3 or a document processing program stored in an  
20 external memory 11, loaded into a RAM 2 and executed, executes the processing of a document containing mixed objects such as graphics, images, text and tables (inclusive of spreadsheets, etc.). The CPU 1 performs overall control of various devices connected to a system  
25 bus 4. An operating system (OS) program, which is the control program of the CPU 1, has been stored in a program ROM of the ROM 3 or in the external memory 11.

Font data, etc. used when the above-mentioned document processing is executed has been stored in a font ROM of the ROM 3 or in the external memory 11. Various data used when the above-mentioned document processing is executed has been stored in a data ROM of the ROM 3 or in the external memory 11. The RAM 2 functions as the main memory and work area of the CPU 1. A keyboard controller (KBC) 5 controls inputs from a keyboard 9 and pointing device, which is not shown. A CRT controller (CRTC) 6 controls the display on a CRT display (CRT) 10. A disk controller (DKC) 7 controls access to the external memory 11, such as a hard disk (HD) or floppy disk (FD), which stores a booting program, various application programs, font data, user files, edited files and a program (referred to as a "printer driver" below) for generating printer control commands. A printer controller (PRTC) 8, which is connected to a printer 1500 via a bidirectional interface 21, executes processing for controlling communication with the printer 1500.

The CPU 1 executes processing to expand (rasterize) outline fonts to a display-information RAM set up in, say, the RAM 2, and is capable of implementing a WYSIWYG (What You See I What You Get) function on CRT 10. Further, on the basis of commands designated by a mouse cursor (not shown) on the CRT 10, the CPU 1 opens various windows that have been registered and executes a

variety of data processing. When printing is executed,  
the user opens a window relating to printing settings,  
sets the printer and sets a print processing method in  
regard to the printer driver, the setting including the  
5 selection of a printing mode.

The structure of printer 1500 will now be  
described.

The printer 1500 is controlled by a CPU 12. On the  
basis of a control program, etc., stored in a program  
10 ROM of a ROM 13 or a control program, etc., stored in an  
external memory 14, the printer CPU 12 outputs an image  
signal, which serves as output information, to a  
printing unit (printer engine) 17 connected to a system  
bus 15. A control program of the CPU 12 is stored in a  
15 program ROM of the ROM 13. Font data used when the  
above-mentioned output information is generated is  
stored in a font ROM of the ROM 13. In case of a  
printer not equipped with the external memory 14 such as  
a hard disk, information utilized in the host computer  
20 3000 is stored in a data ROM of the ROM 13. The CPU 12,  
which can execute processing for communicating with the  
host computer via an input unit 18, is capable of  
notifying the host computer 3000 of information internal  
to the printer 1500. A RAM 19, which functions as the  
25 main memory and work area of the CPU 12, is so adapted  
that memory capacity can be expanded by optional RAM  
connected to an expansion port, not shown. The RAM 19

is used as an area for expanding output information, as  
an area for storing environment data and as an NVRAM  
(non-volatile RAM). The external memory 14, such a hard  
disk (HD) or IC card, has its access controlled by a  
5 memory controller (MC) 20. The external memory 14,  
which is connected to the printer as an option, stores  
font data, an emulation program and form data, etc. It  
should be noted that if the external memory 14 does not  
exist, hard disk per se may be included in the main  
10 controller (MC) 20. Further, a control panel 1501 has  
an array of operation switches and LED indicators. The  
external memory 14 is not limited to a single memory. A  
plurality of these memories can be provided and an  
arrangement may be adopted in which a plurality of  
15 optional font cards or a plurality of external memories  
storing programs for interpreting printer control  
languages of different language systems can be connected  
to the apparatus. Furthermore, the external memory 14  
may have an NVRAM (not shown) for storing printer mode  
20 setting information from the control panel 1501.

Fig. 2 is a functional block diagram for describing  
various functions in a printer control system in which  
the host computer 3000 and printer 1500 are connected  
via a cable or network, as shown in Fig. 1.

25 An application 201, graphic engine 202, printer  
driver 203 and system spooler 204 are retained in the  
external memory 11 of host computer 3000 as files.

These are program modules which, when they are to be executed, are loaded in the RAM 2 and executed by the operating system and by modules which utilize these modules. The application 201 and the printer driver 203  
5 can be stored on a floppy disk or CD-ROM of the external memory 11 or can be stored on the hard disk of the external memory 11 via a network, not shown. The application 201 stored in the external memory 11 is executed upon being loaded in the RAM 2. When the  
10 application 201 performs printing using the printer 1500, output (rendering) is performed utilizing the graphic engine 202, which likewise is capable of being executed upon being loaded in the RAM 2. The graphic engine 202 loads the printer driver 203, which is  
15 prepared for each printer, from the external memory 11 to the RAM 2 and sets the output from the application 201 in the printer driver 203. The graphic engine converts a GDI (Graphic Device Interface) function, which is received from the application 201, to a DDI  
20 (Device Driver Interface) function and outputs the DDI function to the printer driver 203. On the basis of the DDI function received from the graphic engine 202, the printer driver 203 makes a conversion to a control command, e.g., PDL (Page Description Language), that is  
25 capable of being recognized by the printer 1500. The printer control command obtained by the conversion is output to the printer 1500 as print data via a system

spooler 204, which has been loaded in the RAM 2 by the operating system, through an interface 21.

Fig. 4 is a diagram illustrating an example of a display on the control panel 1501 of the printer 1500 according to this embodiment in a case where print data with an accompanying password has been received from the host computer 3000. Print data with an accompanying password is created by incorporating a user ID in print data when the print data is created by the host computer 3000. Upon receiving this print data with an accompanying password, the printer 1500 will execute printing only after an ID (password) identical with the user ID is input to the printer. The example of Fig. 4 illustrates a case where the printer is in a standby state in which two items of print data with accompanying passwords have been received.

The display shown in Fig. 4 includes an area 401 which indicates whether print data is print data with an accompanying password. If the data is print data with an accompanying password, a "locked" icon 407 is displayed in this area. An area 402 displays the time at which print data was received from the host computer 3000, an area 403 displays the job name associated with the print data, an area 404 displays the user name associated with the print data, and an area 405 displays the present status of the print job. In the example of Fig. 4, the status of both print jobs is "WAITING".

Also displayed is a button 406 that allows the user to call an input screen that is for entering a password. Specifically, the printer 1500 is such that if the print data is print data with an accompanying password, processing for printing this print data will not be executed unless the user of printer 1500 enters a password identical with that of the print data with the accompanying password. Thus, the confidentiality of a printout produced by the printer 1500 is maintained.

Fig. 5 is a diagram illustrating an example of the password input screen displayed on the display unit of the control panel 1501 immediately after one item of print data in Fig. 4 is designated and the button 406 is clicked in a state where multiple items of print data are shown waiting in Fig. 4.

An input area 501 in Fig. 5 indicates an area for entering a password. By entering a password in area 501 and clicking an OK button 502, the entered password will be compared with the password that has been assigned to the designated waiting print job. If the password entered in the area 501 matches the password of the corresponding print job, the print job is executed and printing is performed. If the two passwords do not match, a message reading "ENTER CORRECT PASSWORD" is displayed, as indicated at 601 in Fig. 6, whereby the user is prompted to re-enter a password in the input area 501. To cancel print processing, the user clicks a

cancel button 503.

Fig. 7 is a diagram showing an example of the GUI of the printer driver 203 displayed on the display unit 10 of the host computer 3000. Here Fig. 7 illustrates an example of a window display particularly in a case where printing of "print data with password" is set.

By selecting "SECURED PRINT" indicated at 701 in Fig. 7, it becomes possible to designate printing of print data having an accompanying password. Immediately after printing of print data with an accompanying password is designated, a confirmation message of the kind shown in Fig. 8 is displayed. This message allows the user to confirm selection of the setting for printing the print data having the accompanying password and instructs the user to enter a user name and password. Clicking an OK button 801 returns processing to the GUI of Fig. 7.

If a button 702 is clicking in the state shown in Fig. 7, a dialog screen shown in Fig. 9 is displayed. Here the user enters any user name (it is not required that this match the actual name of the user) in a user name input area 901 and enters a password in a password input area 902 (the entered password, however, is not displayed) (see Fig. 10), whereby the user name and password are set for the print data having the accompanying password. In Figs. 9 and 10, an OK button 903 is for finalizing inputs made on the dialog screen,

and a cancel button 904 is for canceling inputs made on the dialog screen.

Fig. 11 is a diagram showing an example of a dialog screen displayed on the display unit 10 immediately after issuance of a print instruction from an application when printing based upon print data with an accompanying password has been selected using the host computer 3000.

The user name entered in the area 901 shown in Fig. 9 is displayed in an area 1101, and the password information entered in area 902 shown in Fig. 9 is displayed as "\*\*\*\*\*". Further, since the printer driver 203 is capable of acquiring the document name from the print data, the printer driver displays the document name ("PRINTER TEST PAGE" in this case) in an area 1103. By using this displayed dialog screen, the user is capable of changing and editing the document name and user name shown in Fig. 11.

In Fig. 12, the document name has been changed from "PRINTER TEST PAGE", which is shown in Fig. 11, to "ABCD". Since the user can thus set any name for the document name or user name, the degree of security can be enhanced also with regard to document names and user names.

Further, by using the dialog screen shown in Fig. 11, the user can set a user name, document name and password whenever printing is performed. If an OK

button 1104 is clicked, printing is executed. If a cancel button 1105 is clicked, on the other hand, the printing operation is canceled.

Fig. 13 is a flowchart illustrating print processing executed by the host computer 3000 according to the first embodiment of the invention.

If a print instruction is received from the application 201 at step S101 in Fig. 13, control proceeds to step S102, at which the host computer determines whether the print job is for printing based upon print data with an accompanying password. This is achieved by determining whether "SECURED PRINT" has been designated at 701 in Fig. 7 and whether the OK button 801 has been clicked in the display of Fig. 8. If printing based upon print data with an accompanying password has been designated, control proceeds to step S103; otherwise, control proceeds to step S109.

The dialog screen shown in Fig. 9 is displayed at step S103 and the host computer waits for an input event from the user employing the keyboard 9. Next, control proceeds to step S104. If the specified user name and password are finalized by the OK button in Fig. 9 and the OK button 1104 in Fig. 11 is clicked, the host computer judges that the input event is a print request, adds on the entered password information and executes print processing to send the results to the printer 1500 as a request to execute printing of the print data that

uses the entered user name and document name.

If it is determined at step S104 that a print request has not been issued, control proceeds to step S105, at which it is determined whether the input event  
5 is a request to cancel printing. More specifically, the host computer determines whether the cancel button 1104 in Fig. 11 has been clicked. If this button has been clicked, control proceeds to step S107, at which the application is sent a print cancel instruction to  
10 terminate processing.

If it is found at step S105 that a request to cancel printing has not been issued, then control proceeds to step S106. Here the host computer determines whether the input event is an operation  
15 performed by the user for entering a document name, user name and password. If the answer is "YES", control proceeds to step S108, where the entered items of information are held in the corresponding memory areas (in RAM 2).

20 Fig. 14 is a flowchart illustrating print processing in the printer 1500 according to this embodiment.

The printer determines at step S201 whether a print job has been received from the host computer 3000. If a  
25 print job has been received, control proceeds to step S202, at which the printer stores the received print data in the RAM 19 by inputting it from the input unit

18. Next, at step S203, the printer determines whether the received print data is print data with an accompanying password. If the answer is "YES", control proceeds to step S204. If the answer is "NO", on the other hand, control proceeds to step S207, where the print job is executed and printing is performed.

In case of data with an accompanying password, control proceeds to step S204. Here reception time, job name, user name and status of each job are displayed, as shown for example in Fig. 4, on the display unit of control panel 1501 on printer 1500. Control then proceeds to step S205. If a plurality of print jobs are being displayed, one of these print jobs is designated by a cursor or the like and password processing for executing this print job is executed. When only one print job is being displayed, password processing for executing this print job is executed. Here the dialog screen shown in Fig. 5 is displayed on the control panel 1501 and the printer waits for entry of the password corresponding to the print job.

If the password has been entered, control proceeds to step S206, at which the printer compares the entered password with the password assigned to the print job and determines whether the two match. When there is a match, control proceeds to step S207 and the printer executes the designated print job. If a match is not found at step S207, however, control proceeds to step

S208, where the dialog screen shown in Fig. 6 is displayed to prompt the user to enter the correct password. The processing of steps S205 to S206 and S208 is executed until the correct password is entered.

- 5 Concurrently, processing for receiving the next item of print data is executed at steps S201 to S204.

Thus, in accordance with the printing system of the first embodiment, the host computer 3000 transmits print data with an accompanying password to the printer 1500.

- 10 Upon receiving an input of the password corresponding to this print job, the printer 1500 proceeds to execute the print job and to perform printing. Further, since the host computer 3000 can set the document name, user name and password of the print job to any values, the job can  
15 be printed in such a manner that a third party cannot possibly ascertain who created the document nor the content of the document.

[Second Embodiment]

- A printing system according to this embodiment may  
20 have an arrangement which, as shown in Fig. 3, spools print data from the application 201 temporarily in the form of intermediate code data. This arrangement is provided as an addition to the system comprising the printer 1500 and host computer 3000 implemented by the  
25 programs shown in Fig. 2.

Fig. 3 is a block diagram illustrating the structure of a program executed by the host computer

3000 according to a second embodiment of the invention.

A spool file 303 comprising intermediate codes is generated temporarily when a print instruction is sent from the graphic engine 202 to the printer driver 203 by the application 201. In the arrangement of Fig. 2 according to the first embodiment, the application 201 is freed from print processing at the moment the printer driver 203 finishes converting all print instructions from the graphic engine 202 to control commands for the printer 1500. In the arrangement of Fig. 3, on the other hand, the application 201 is freed from print processing at the moment a spooler 302 in the printer driver 203 converts all print instructions to intermediate code data and outputs the code data to a spool file 303. Ordinarily the arrangement according to the second embodiment requires a shorter period of time for print processing than the arrangement of the first embodiment.

Further, in the system shown in Fig. 3, the content of the spool file 303 can be manipulated. As a result, it is possible to realize multifarious page handling functions for print data from the application 201. For example, the print data can be enlarged or reduced in size and a plurality of pages may be printed upon being reduced to the size of a single page. Further, as will be described later, it is possible to combine print jobs, to perform editing such as page substitution and

to preview data. Furthermore, by analyzing data to render a color/monochrome decision, it is possible to perform resource conserving printing that takes the printer function into account and to improve

5 performance.

In order to attain these objectives, the printing system of the arrangement shown Fig. 2 is expanded in such a manner that print data is spooled in the form of intermediate codes as shown in Fig. 3. In order to  
10 manipulate the print data, the operator usually makes settings using a window provided by the printer driver 203.

The basic processing of the expanded scheme shown in Fig. 3 will now be described.

15 First, the print instructions from the graphic engine 202 are accepted by a dispatcher 301. In a case where a print instruction that the dispatcher 301 has accepted from the graphic engine 202 is a print instruction that the application 201 issued to the  
20 graphic engine 202, the dispatcher 301 loads the spooler 302, which has been stored in the external memory 11, into the RAM 2 and sends the print instruction to the spooler 302 and not the printer driver 203.

As a result, the spooler 302 converts the accepted  
25 print instruction to an intermediate code and outputs the code to the spool file 303. Further, the spooler 302 acquires the manipulation settings, which relate to

print data set in the printer driver 203, from the  
printer driver 203 and stores the data in the spool file  
303. Though the spool file 303 is generated as a file  
in the external memory 11, the file may be generated in  
5 the RAM 2. Furthermore, the spooler 302 loads a spool  
file manager 304, which has been stored in the external  
memory 11, and notifies the spool file manager 304 of  
the status of spool file generation. In accordance with  
the content of the manipulation settings relating to the  
10 print data stored in the spool file 303, the spool file  
manager 304 subsequently determines whether printing can  
be performed.

When the spool file manager 304 has judged that  
printing can be performed utilizing the graphic engine  
15 202, the spool file manager 304 loads a despooler 305,  
which has been stored in the external memory 11, into  
the RAM 2 and instructs the despooler 305 to perform  
printing of the intermediate codes described in the  
spool file 303. As a result, in accordance with the  
20 content of manipulation settings included in the spool  
file 303, the despooler 305 manipulates the intermediate  
codes contained in the spool file 303 and outputs them  
again via the graphic engine 202.

In a case where a print instruction which the  
25 dispatcher 301 receives from the graphic engine 202 is a  
print instruction sent from the despooler 305 to the  
graphic engine 202, the dispatcher 301 sends the print

instruction to the printer driver 203 and not the spooler 302. As a result, the printer driver 203 generates a printer control command and sends the command to the system spooler 204.

5 Furthermore, according to the second embodiment, the expanded system described thus far is provided with a previewer 306 and a settings changing editor 307, as shown in Fig. 3, to make it possible to perform previewing, to change print settings and to combine a  
10 plurality of jobs.

In order to perform print previewing, change print settings and combine multiple jobs, "EDIT AND PREVIEW" is designated in the properties of the printer driver 203, as shown at 1301 in Fig. 15, using a pull-down menu  
15 serving as means for designating an output destination.

The content thus set in the properties of the printer driver 203 is stored as a settings file in the structure provided by the operating system (in the Windows operating system, the structure is referred to  
20 as "DEVMODE"). This structure includes a setting as to whether the spool file manager 304 is to perform storage in the manipulation settings contained in the spool file 303. The spool file manager 304 reads in the manipulation settings via the printer driver 203 and, if  
25 the store designation has been made, generates a page description file and a job settings file and stores these in the spool file 303 in the manner set forth

above.

As shown in Fig. 16, the window screen of the spool file manager 304 pops up and the jobs that have been spooled in the spool file 303 are displayed in list form.

Fig. 16 shows an example in which four print jobs have been spooled. A print job can be operated on by designating a menu bar or an immediately underlying menu icon. The number of operations of the menu bar and the number of operations of the menu icons are the same.

There are 11 types of operations available when a job has been selected, namely: PRINT; PROOF PRINT, in which a spool file of intermediate code is left as is and printed; PRINT PREVIEW, which is for viewing an output preview of a job that takes print settings into consideration; DELETE, which is for deleting a spool file of intermediate code; DUPLICATE, which is for generating a copy of a spool file of intermediate code; COMBINE, in which a plurality of jobs of spool files of intermediate code are combined into a single job; SEPARATE, which is for separating a combined job into the plurality of original jobs; CHANGE PRINT SETTINGS, which is for changing the print settings (layout settings, finishing settings, etc.) of an individual job or combined job; MOVE TO TOP, in which the print sequence of a certain job is changed so that the job is processed first; MOVE TO PREVIOUS, in which the print

sequence of a certain job is changed to move up the job  
by one job; MOVE TO NEXT, in which the print sequence of  
a certain job is changed to move down the job by one  
job; and MOVE TO LAST, in which the print sequence of a  
5 certain job is changed so that the job is processed  
last.

In a case where preview of a certain individual job  
or combined job has been designated on the window screen  
(Fig. 16) of the spool file manager 304, the previewer  
10 306 is loaded and the previewer 306 is instructed to  
execute processing for previewing the job of  
intermediate code described in the spool file 303.

The previewer 306 sequentially reads in the page  
description file (PDF) of intermediate code included in  
15 the spool file 303, manipulates the data in accordance  
with the manipulation settings information included in  
the job settings file (SDF) stored in the spool file  
303, and outputs the GDI functions to the graphic engine  
202. The graphic engine 202 outputs the rendered data  
20 to its own client area, thereby making it possible to  
produce an output on the screen.

Further, it is possible for the graphic engine 202  
to perform appropriate rendering in conformity with the  
designated printer. This means that in a manner similar  
25 to that of the despooler 305, the previewer 306 can be  
implemented by a method of manipulating the intermediate  
code, which is contained in the spool file 303, in

0904747 .050304  
TOP SECRET

accordance with the content of the manipulation settings  
contained in the spool file 303, and outputting the  
results utilizing the graphic engine 202. The  
manipulation settings that have been configured by the  
5 printer driver 203 are stored in the spool file 303 as a  
job settings file and the data of the page description  
file is machined and output based upon the job settings  
file. As a result, depending upon how the actual  
rendering data is printed and, in a case where Nup  
10 (processing for reducing the size of N-number of  
physical pages to a single page, placing these on the  
single page and printing the same) has been designated,  
a case where double-sided printing has been designated,  
a case where duplicate printing has been designated and  
15 a case where stamping has been designated, the user can  
be provided with a print preview that closely  
approximates what will be output by the printer 1500.

It should be noted that the print preview function  
possessed by conventional application software for  
20 document creation or the like performs rendering based  
upon page settings in the application. As a  
consequence, the print settings at the printer driver  
203 are not reflected and the user cannot be made to  
recognize a preview of printing that will actually be  
25 produced.

By executing the preview processing as described  
above, a large preview of print manipulation settings

contained in the spool file 303 will be displayed on the screen by the previewer 306, as shown in Fig. 17.

Thereafter, in response to a command from the user to quit this display, the previewer 306 is closed and

5 control shifts to the window screen (Fig. 16) of the spool file manager 304.

If the user performs printing in accordance with the content displayed by the previewer 306, a print request can be issued by designating "PRINT" or "PROOF  
10 PRINT" on the spool file manager 304. As described above, the print request is such that a page description file is manipulated by the despooler 305 based upon a job settings file to thereby generate the GDI function, the latter is sent to the graphic engine 202 and a print  
15 instruction is sent to the printer driver 203 via the dispatcher 301, whereby printing is executed.

Processing that follows the spooling of print data in a case where printing of print data with an accompanying password is performed in this spool system  
20 will be described with reference to the flowchart shown in Fig. 18.

Fig. 18 is a flowchart illustrating print processing executed by the host computer 3000 according to the second embodiment of the invention.

25 If the spool file manager 304 receives an event input at step S301, control proceeds to step S302, at which the spool file manager 304 discriminates the type

of event. If the event is a print instruction, control proceeds to step S303; otherwise, control proceeds to step S304. The spool file manager 304 activates the despooler 305 and issues a print command at step S303.

5 The despooler 305 at this time operates in the same manner as the application indicated by the flowchart of Fig. 13. As a result, the password information dialog screen for when printing is performed is presented again when a print request is sent to the printer driver 203  
10 via the dispatcher 301.

If it is found at step S302 that a print request has not been issued, control proceeds to step S304, at which it is determined whether the input event is a request to combine jobs. If the answer is "YES",  
15 control proceeds to step S305; otherwise, control proceeds to step S306 and other processing is executed. At step S305, a plurality of selected jobs are treated as a combined job. More specifically, a print request is issued (the processing of step S303 is executed) one  
20 time by the single despooler 305 for the spool file 303 of these multiple jobs.

It should be noted that since the print data from the application 201 is delivered to the spooler 302 by the dispatcher 301, data has not been sent to the  
25 printer driver 203 at this time. That is, even in a case where a plurality of jobs are combined and printed as in Fig. 16, display of a dialog screen is not

presented for each job that prevailed prior to being combined. Rather, a dialog screen is displayed after the jobs are combined into a single job.

The processing method of the spool system in a case where the cancel button 1105 of Fig. 11 is clicked through a method similar to that of the first embodiment will be described with reference to the flowchart of Fig. 19.

Fig. 19 is a flowchart which basically illustrates processing in a case where the cancel button 1105 is clicked in the flowchart of Fig. 13.

Processing after a print cancel request has been entered at step S105 differs from that of the flowchart of Fig. 13. If a print cancel request has been entered, control proceeds to step S401, at which an instruction for canceling printing is delivered to the despooler 305 and not the application 201. Next, at step S402, the despooler 305 notifies the spool file manager 304 of cancellation of printing and unloads the program from the RAM 2. Control then proceeds to step S403, at which the spool file manager 304 erases the spool file 303 that was generated by the despooler 302 and unloads the RAM 2. As a result, even in a case where the spool system is expanded in a job accounting system, job accounting is carried out without holding the spool file 303 in the external memory 11.

The present invention can be applied to a system

constituted by a plurality of devices (e.g., a host computer, interface, reader, printer, etc.) or to an apparatus comprising a single device (e.g., a copier or facsimile machine, etc.).

5           Furthermore, it goes without saying that the object of the invention is attained also by supplying a storage medium storing the program codes of the software for performing the functions of the foregoing embodiments to a system or an apparatus, reading the program codes with  
10 a computer (e.g., a CPU or MPU) of the system or apparatus from the storage medium, and then executing the program codes. In this case, the program codes read from the storage medium implement the novel functions of the embodiments and the storage medium storing the  
15 program codes constitutes the invention.

Examples of storage media that can be used for supplying the program code are a floppy disk, hard disk, optical disk, magneto-optical disk, CD-ROM, CD-R, magnetic tape, non-volatile type memory card or ROM,  
20 etc. Furthermore, besides the case where the aforesaid functions according to the embodiments are implemented by executing the program codes read by a computer, it goes without saying that the present invention covers a case where an operating system or the like running on  
25 the computer performs a part of or the entire process in accordance with the designation of program codes and implements the functions according to the embodiments.

-

It goes without saying that the present invention further covers a case where, after the program codes read from the storage medium are written in a function expansion board inserted into the computer or in a

5 memory provided in a function expansion unit connected to the computer, a CPU or the like contained in the function expansion board or function expansion unit performs a part of or the entire process in accordance with the designation of program codes and implements the

10 function of the above embodiments.

Thus, in accordance with the present invention, as described above, a printing system in which a password is assigned to a print job and a printout is obtained by a printer by inputting the password is provided with

15 means for changing a user name or a document name. This has the effect of enhancing the security of documents stored in a printer.

The present invention is not limited to the above embodiments and various changes and modifications can be

20 made within the spirit and scope of the present invention. Therefore, to apprise the public of the scope of the present invention, the following claims are made.
